General Description

The SX1211 is a low cost single-chip transceiver operating in the frequency ranges from 863-870, 902-928 MHz and 950-960 MHz. The SX1211 is optimized for very low power consumption (3mA in receiver mode). It incorporates a baseband modem with data rates up to 200 kb/s. Data handling features include a sixty-four byte FIFO, packet handling, automatic CRC generation and data whitening. Its highly integrated architecture allows for minimum external component count whilst maintaining design flexibility. All major RF communication parameters are programmable and most of them may be dynamically set. It complies with European (ETSI EN 300-220 V2.1.1) and North American (FCC part 15.247 and 15.249) regulatory standards.

Features

- Low Rx power consumption: 3mA
- Low Tx power consumption: 25 mA @ +10 dBm
- Good reception sensitivity: down to -107 dBm at 25 kb/s in FSK, -113 dBm at 2kb/s in OOK
- Programmable RF output power: up to +12.5 dBm in 8 steps
- Packet handling feature with data whitening and automatic CRC generation
- Wide RSSI (Received Signal Strength Indicator) dynamic range, 70dB from Rx noise floor
- Bit rates up to 200 kb/s, NRZ coding
- On-chip frequency synthesizer
- FSK and OOK modulation
- Incoming sync word recognition
- Built-in Bit-Synchronizer for incoming data and clock synchronization and recovery
- 5 x 5 mm TQFN package
- Optimized Circuit Configuration for Low-cost applications

- TQFN-32 package – Operating range [-40;+85°C]
- T refers to Lead Free packaging
- This device is WEEE and RoHS compliant

Applications

- Wireless alarm and security systems
- Wireless sensor networks
- Automated Meter Reading
- Home and building automation
- Industrial monitoring and control
- Remote Wireless Control

This product datasheet contains a detailed description of the SX1211 performance and functionality. Please consult the Semtech website for the latest updates or errata.

1. General Description

The SX1211 is a single chip FSK and OOK transceiver capable of operation in the 863-870 MHz and 902-928 MHz license free ISM frequency bands, as well as the 950 - 960 MHz frequency band. It complies with both the relevant European and North American standards, EN 300-220 V2.1.1 (June 2006 release) and FCC Part 15 (10-1-2006 edition). A unique feature of this circuit is its extremely low current consumption in receiver mode of only 3mA (typ). The SX1211 comes in a 5x5 mm TQFN-32 package.

Note: pin 13 (Test 8) can be used as an manual reset trigger. See section 7.4.2 for details on its use.
2. Electrical Characteristics

2.1. ESD Notice

The SX1211 is a high performance radio frequency device. It satisfies:

- Class 2 of the JEDEC standard JESD22-A114-B (Human Body Model), except on pins 3-4-5-27-28-29-31 where it satisfies Class 1A.
- Class III of the JEDEC standard JESD22-C101C (Charged Device Model) on all pins.

It should thus be handled with all the necessary ESD precautions to avoid any permanent damage.

2.2. Absolute Maximum Ratings

Stresses above the values listed below may cause permanent device failure. Exposure to absolute maximum ratings for extended periods may affect device reliability.

Note: on pin 10 (XTAL_P) and 11 (XTAL_N), maximum voltages of 1.8V can be applied.
3. Architecture Description

This section describes in depth the architecture of this ultra low-power transceiver:

![Diagram of SX1211](image)

Figure 3: SX1211 Detailed Block Diagram

### 3.1. Power Supply Strategy

To provide stable sensitivity and linearity characteristics over a wide supply range, the SX1211 is internally regulated. This internal regulated power supply structure is described below:
To ensure correct operation of the regulator circuit, the decoupling capacitor connection shown in Figure 4 is required. These decoupling components are recommended for any design.

3.2. Frequency Synthesis Description

The frequency synthesizer of the SX1211 is a fully integrated integer-N type PLL. The PLL circuit requires only five external components for the PLL loop filter and the VCO tank circuit.

3.2.1. Reference Oscillator

The SX1211 embeds a crystal oscillator, which provides the reference frequency for the PLL. The recommended crystal specification is given in section 7.1.

3.2.2. CLKOUT Output

The reference frequency, or a sub-multiple of it, can be provided on CLKOUT (pin 19) by activating the bit OSCParam_Clkout_on. The division ratio is programmed through bits OSCParam_Clkout_freq. The two applications of the CLKOUT output are:

- To provide a clock output for a companion uC, thus saving the cost of an additional oscillator. CLKOUT can be made available in any operation mode, except Sleep mode, and is automatically enabled at power-up.
- To provide an oscillator reference output. Measurement of the CLKOUT signal enables simple software trimming of the initial crystal tolerance.

Note: To minimize the current consumption of the SX1211, ensure that the CLKOUT signal is disabled when unused.
3.2.3. PLL Architecture

The crystal oscillator (XO) forms the reference oscillator of an Integer-N Phase Locked Loop (PLL), whose operation is discussed in the following section. Figure 5 shows a block schematic of the SX1211 PLL. Here the crystal reference frequency and the software controlled dividers R, P and S determine the output frequency of the PLL.

![Figure 5: Frequency Synthesizer Description](image)

The VCO tank inductors are connected on an external differential input. Similarly, the loop filter is also located externally. However, there is an internal 8pF capacitance at VCO input that should be subtracted from the desired loop filter capacitance.

The output signal of the VCO is used as the input to the local oscillator (LO) generator stage, illustrated in Figure 6. The VCO frequency is subdivided and used in a series of up (down) conversions for transmission (reception).

![Figure 6: LO Generator](image)

3.2.4. PLL Tradeoffs

With an integer-N PLL architecture, the following criterion must be met to ensure correct operation:

- The comparison frequency, Fcomp, of the Phase Frequency Detector (PFD) input must remain higher than six times the PLL bandwidth (PLLBW) to guarantee loop stability and to reject harmonics of the comparison frequency Fcomp. This is expressed in the inequality:

\[
\frac{F_{comp}}{6} \leq PLLBW
\]

- However the PLLBW has to be sufficiently high to allow adequate PLL lock times
- Because the divider ratio R determines Fcomp, it should be set close to 119, leading to Fcomp≈100 kHz which will ensure suitable PLL stability and speed.
With the recommended Bill Of Materials (BOM) of the reference design of section 7.5.3, the PLL prototype is the following:

- $64 \leq R \leq 169$
- $S < P+1$
- $\text{PLLBW} = 15 \text{ kHz nominal}$
- Startup times and reference frequency spurs as specified.

### 3.2.5. Voltage Controlled Oscillator

The integrated VCO requires only two external tank circuit inductors. As the input is differential, the two inductors should have the same nominal value. The performance of these components is important for both the phase noise and the power consumption of the PLL. It is recommended that a pair of high Q factor inductors is selected. These should be mounted orthogonally to other inductors (in particular the PA choke) to reduce spurious coupling between the PA and VCO. In addition, such measures may reduce radiated pulling effects and undesirable transient behavior, thus minimizing spectral occupancy. Note that ensuring a symmetrical layout of the VCO inductors will further improve PLL spectral purity.

For best performance wound type inductors, with tight tolerance, should be used as described in section 7.5.3.

#### 3.2.5.1. SW Settings of the VCO

To guarantee the optimum operation of the VCO over the SX1211’s frequency and temperature ranges, the following settings should be programmed into the SX1211:

<table>
<thead>
<tr>
<th>Target channel (MHz)</th>
<th>863-870</th>
<th>902-915</th>
<th>915-928</th>
<th>950-960</th>
</tr>
</thead>
<tbody>
<tr>
<td>Freq_band</td>
<td>10</td>
<td>00</td>
<td>01</td>
<td>10</td>
</tr>
</tbody>
</table>

*Table 10: MCParm_Freq_band Setting*

#### 3.2.5.2. Trimming the VCO Tank by Hardware and Software

To ensure that the frequency band of operation may be accurately addressed by the R, P and S dividers of the synthesizer, it is necessary to ensure that the VCO is correctly centered. Note that for the reference design (see section 7.5) no centering is necessary. However, any deviation from the reference design may require the optimization procedure, outlined below, to be implemented. This procedure is simplified thanks to the built-in VCO trimming feature which is controlled over the SPI interface. This tuning does not require any RF test equipment, and can be achieved by simply measuring $V_{tune}$, the voltage between pins 6 (LFM) and 7 (LFP).

The VCO is centered if the voltage is within the range:

$$50 \leq V_{tune}(mV) \leq 150$$

Note that this measurement should be conducted when in transmit mode at the center frequency of the desired band (for example ~867 MHz in the 863-870 MHz band), with the appropriate MCParm_Freq_band setting.

If this inequality is not satisfied then adjust the MCParm_VCO_trim bits from 00 whilst monitoring $V_{tune}$. This allows the VCO voltage to be trimmed in $\pm 60 \text{ mV increments}$. Should the desired voltage range be inaccessible, the voltage may be adjusted further by changing the tank circuit inductance value. Note that an increase in inductance will result in an increase $V_{tune}$.  

---

Rev 8 – February 2013  
Page 15 of 92  
www.semtech.com
Note for mass production: The VCO capacitance is piece to piece dependant. As such, the optimization proposed above should be verified on several prototypes, to ensure that the population is centered on 100 mV.

### 3.2.6. PLL Loop Filter

To adequately reject spurious components arising from the comparison frequency $F_{\text{comp}}$, an external 2\textsuperscript{nd} order loop filter is employed.

![Loop Filter Diagram](image)

**Figure 7: Loop Filter**

Following the recommendations made in section 3.2.4, the loop filter proposed in the reference design’s bill of material on section 7.5.3 should be used. The loop filter settings are frequency band independent and are hence relevant to all implementations of the SX1211.

### 3.2.7. PLL Lock Detection Indicator

The SX1211 also features a PLL lock detect indicator. This is useful for optimizing power consumption, by adjusting the synthesizer wake up time (TS_FS), since the PLL startup time is lower than specified under nominal conditions. The lock status can be read on bit IRQParam_PLL_lock, and must be cleared by writing a “1” to this same register. In addition, the lock status can be reflected in pin 23 PLL_LOCK, by setting the bit IRQParam_Enable_lock_detect.

### 3.2.8. Frequency Calculation

As shown in Figure 5 the PLL structure comprises three different dividers, R, P and S, which set the output frequency through the LO. A second set of dividers is also available to allow rapid switching between a pair of frequencies: $R_1/P_1/S_1$ and $R_2/P_2/S_2$. These six dividers are programmed by six bytes of the register MCParam from addresses 6 to 11.

#### 3.2.8.1. FSK Mode

The following formula gives the relationship between the local oscillator, and R, P and S values, when using FSK modulation.

$$F_{\text{rf}, \ fsk} = \frac{9}{8} F_{\text{lo}}$$

$$F_{\text{rf}, \ fsk} = \frac{9}{8} F_{\text{xtal}} \left[75(P + 1) + S\right]$$

#### 3.2.8.2. OOK Mode

Due to the manner in which the baseband OOK symbols are generated, the signal is always offset by the FSK frequency deviation ($F_{\text{dev}}$ - as programmed in MCParam\_Freq\_dev). Hence, the center of the transmitted OOK signal is:
Consequently, in receive mode, due to the low intermediate frequency (Low-IF) architecture of the SX1211 the frequency should be configured so as to ensure the correct low-IF receiver baseband center frequency, IF2.

\[
F_{f, ook, rx} = \frac{9}{8} (F_{o} - IF2)
\]

\[
F_{f, ook, rx} = \frac{9 \cdot F_{xtal}}{8 \cdot (R + 1)} [75(P + 1) + S] - IF2
\]

Note that from Section 3.4.4, it is recommended that IF2 be set to 100 kHz.
3.3. Transmitter Description

The SX1211 is set to transmit mode when MCParam_Chip_mode = 100.

![Transmitter Architecture Diagram]

**Figure 8: Transmitter Architecture**

### 3.3.1. Architecture Description

The baseband I and Q signals are digitally generated by a DDS whose digital to analog converters (DAC) followed by two anti-aliasing low-pass filters transform the digital signal into analog in-phase (I) and quadrature (Q) components whose frequency is the selected frequency deviation (Fdev).

![I(t), Q(t) Overview Diagram]

**Figure 9: I(t), Q(t) Overview**

In FSK mode, the relative phase of I and Q is switched by the input data between -90° and +90° with continuous phase. The modulation is therefore performed at this initial stage, since the information contained in the phase difference will be converted into a frequency shift when the I and Q signals are up-converted in the first mixer stage. This first up-conversion stage is duplicated to enhance image rejection. The FSK convention is such that:

\[
\begin{align*}
\text{DATA} = '1' & \Rightarrow \text{Frf} + \text{Fdev} \\
\text{DATA} = '0' & \Rightarrow \text{Frf} - \text{Fdev}
\end{align*}
\]
In OOK mode, the phase difference between the I and Q channels is kept constant (independent of the transmitted data). Thus, the first stage of up-conversion creates a fixed frequency signal at the low IF = Fdev (This explains why the transmitted OOK spectrum is offset by Fdev).

OOK Modulation is accomplished by switching on and off the PA and PA regulator stages. By convention:

\[
\text{DATA} = \text{"1"} \Rightarrow \text{PAon} \\
\text{DATA} = \text{"0"} \Rightarrow \text{PAoff}
\]

After the interpolation filters, a set of four mixers combines the I and Q signals and converts them into a pair of complex signals at the second intermediate frequency, equal to 1/8 of the LO frequency, or 1/9 of the RF frequency. These two new I and Q signals are then combined and up-converted to the final RF frequency by two quadrature mixers fed by the LO signal. The signal is pre-amplified, and then the transmitter output is driven by a final power amplifier stage.

### 3.3.2. Bit Rate Setting

In Continuous transmit mode, setting the Bit Rate is useful to determine the frequency of DCLK. As explained in section 5.3.2, DCLK will trigger an interrupt on the uC each time a new bit has to be transmitted.

\[
BR = \frac{F_{XTAL}}{64 \times [1 + \text{val(MCParam BR)}]}
\]

### 3.3.3. Alternative Settings

Bit rate, frequency deviation and TX interpolation filter settings are a function of the reference oscillator crystal frequency, \( F_{XTAL} \). Settings other than those programmable with a 12.8 MHz crystal can be obtained by selection of the correct reference oscillator frequency. Please contact your local Semtech representative for further details.

### 3.3.4. Fdev Setting in FSK Mode

The frequency deviation, \( F_{dev} \), of the FSK transmitter is programmed through bits \( \text{MCParam}_\text{Freq_dev} \):

\[
F_{dev} = \frac{F_{XTAL}}{32 \times [1 + \text{val(MCParam}_\text{Freq}_\text{dev})]}
\]

For correct operation the modulation index \( \beta \) should be such that:

\[
\beta = 2 \times \frac{F_{dev}}{BR} \geq 2
\]

It should be noted that for communications between a pair of SX1211s, that \( F_{dev} \) should be at least 33 kHz to ensure a correct operation on the receiver side.

### 3.3.5. Fdev Setting in OOK Mode

\( F_{dev} \) has no physical meaning in OOK transmit mode. However, as has been shown - due to the DDS baseband signal generation, the OOK signal is always offset by “-Fdev” (see formulas is section 3.2.8). It is suggested that \( F_{dev} \) retains its default value of 100 kHz in OOK mode.
3.3.6. Interpolation Filter

After digital to analog conversion, both I and Q signals are smoothed by interpolation filters. This block low-pass filters the digitally generated signal, and prevents the alias signals from entering the modulators. Its bandwidth can be programmed with the register RXParam_InterpFiltTx, and should be set to:

\[
BW = \frac{3 \times (F_{dev} + \frac{BR}{2})}{2}
\]

Where \(F_{dev}\) is the programmed frequency deviation as set in MCParam_Freq_dev, and \(BR\) is the physical Bit Rate of transmission.

Notes:
- Low interpolation filter bandwidth will attenuate the baseband I/Q signals thus reducing the power of the FSK signal. Conversely, excessive bandwidth will degrade spectral purity.
- For the wideband FSK modulation, for example when operating in DTS mode, the recommended filter setting can not be reached. However, the impact upon spectral purity will be negligible, due to the already wideband channel.

3.3.7. Power Amplifier

The Power Amplifier (PA) integrated in the SX1211 operates under a regulated voltage supply of 1.8 V. The external PA choke inductor is biased by an internal regulator output made available on pin 29 (VR_PA). Thanks to these features, the PA output power is consistent over the power supply range. This is important for mobile applications where this allows both predictable RF performance and battery life.

3.3.7.1. Rise and Fall Times Control

In OOK mode, the PA ramp times can be accurately controlled through the MCParam_PA_ramp register. Those bits directly control the slew rate of VR_PA output (pin 29).

Table 11: PA Rise/Fall Times

3.3.7.2. Optimum Load Impedance

As the PA and the LNA front-ends in the SX1211 share the same Input/Output pin, they are internally matched to approximately 50 $\Omega$.

Please refer to the reference design section for an optimized PA load setting.
3.3.7.3. Suggested PA Biasing and Matching

The recommended PA bias and matching circuit is illustrated below:

![Recommended PA Biasing and Output Matching](image)

Figure 12: Recommended PA Biasing and Output Matching

Please refer to section 7.5.3 of this document for the optimized matching arrangement for each frequency band.

3.3.8. Common Input and Output Front-End

The receiver and the transmitter share the same RFIO pin (pin 31). Figure 13 below shows the configuration of the common RF front-end.

- In transmit mode, the PA and the PA regulator are active, with the voltage on the VR_PA pin equal to the nominal voltage of the regulator (1.8 V). The external inductance is used to bias the PA.
- In receive mode, both PA and PA regulator are off and VR_PA is tied to ground. The external inductance LT1 is then used to bias the LNA.

![Front-end Description](image)

Figure 13: Front-end Description
3.4. Receiver Description

The SX1211 is set to receive mode when MCPram_Chip_mode = 011.

![Receiver Architecture](image)

**Figure 14: Receiver Architecture**

### 3.4.1. Architecture

The SX1211 receiver employs a super-heterodyne architecture. Here, the first IF is \( \frac{1}{9} \) of the RF frequency (approximately 100MHz). The second down-conversion down-converts the I and Q signals to base band in the case of the FSK receiver (Zero IF) and to a low-IF (IF2) for the OOK receiver.

![FSK Receiver Setting](image)

**Figure 15: FSK Receiver Setting**

![OOK Receiver Setting](image)

**Figure 16: OOK Receiver Setting**

After the second down-conversion stage, the received signal is channel-select filtered and amplified to a level adequate for demodulation. Both FSK and OOK demodulation are available. Finally, an optional Bit Synchronizer (BitSync) is provided, to be supply a synchronous clock and data stream to a companion uC in Continuous mode,
or to fill the FIFO buffers with glitch-free data in Buffered mode. The operation of the receiver is now described in detail.

Note: Image rejection is achieved by the SAW filter.

### 3.4.2. LNA and First Mixer

In receive mode, the RFIO pin is connected to a fixed gain, common-gate, Low Noise Amplifier (LNA). The performance of this amplifier is such that the Noise Figure (NF) of the receiver can be estimated to be ≈ 7 dB.

### 3.4.3. IF Gain and Second I/Q Mixer

Following the LNA and first down-conversion, there is an IF amplifier whose gain can be programmed from -13.5 dB to 0 dB in 4.5 dB steps, via the register MCParm_IF_gain. The default setting corresponds to 0 dB gain, but lower values can be used to increase the RSSI dynamic range. Refer to section 3.4.7 for additional information.

### 3.4.4. Channel Filters

The second mixer stages are followed by the channel select filters. The channel select filters have a strong influence on the noise bandwidth and selectivity of the receiver and hence its sensitivity. Each filter comprises a passive and active section.

#### 3.4.4.1. Passive Filter

Each channel select filter features a passive second-order RC filter, with a bandwidth programmable through the bits RXParam_PassiveFilt. As the wider of the two filters, its effect on the sensitivity is negligible, but its bandwidth has to be setup instead to optimize blocking immunity. The value entered into this register sets the single side bandwidth of this filter. For optimum performance it should be set to 3 to 4 times the cutoff frequency of the active Butterworth (or polyphase) filter described in the next section.

\[
3 * Fc_{ButterFilt} \leq BW_{passive, filter} \leq 4 * Fc_{ButterFilt}
\]

#### 3.4.4.2. Active Filter

The 'fine' channel selection is performed by an active, third-order, Butterworth filter, which acts as a low-pass filter for the zero-IF configuration (FSK), or a complex polyphase filter for the Low-IF (OOK) configuration. The RXParam_PolypFilt_on bit enables/disables the polyphase filter.

![Figure 17: Active Channel Filter Description](image-url)
As can be seen from Figure 17, the required bandwidth of this filter varies between the two demodulation modes.

- **FSK mode**: The 99% energy bandwidth of an FSK modulated signal is approximated to be:

  \[ BW_{99\%,FSK} = 2 \times \left[ F_{dev} + \frac{BR}{2} \right] \]

  The bits `RXParam_ButterFilt` set `fc`, the cutoff frequency of the filter. As we are in a Zero-IF configuration, the FSK lobes are centered around the virtual “DC” frequency. The choice of `fc` should be such that the modulated signal falls in the filter bandwidth, anticipating the Local Oscillator frequency drift over the operating temperature and aging of the device:

  \[ 2 \times fc > BW_{99\%,FSK} + LO_{drifts} \]

  Please refer to the charts in section 3.4.5 for an accurate overview of the filter bandwidth vs. setting.

- **OOK mode**: The 99% energy bandwidth of an OOK modulated signal is approximated to be:

  \[ BW_{99\%,OOK} = \frac{2}{T_{bit}} = 2BR \]

  The bits `RXParam_PolyPfilt_center` set `fo`, the center frequency of the polyphase filter when activated. `fo` should always be chosen to be equal to the low Intermediate Frequency of the receiver (IF2). This is why, in the GUI described in section 7.2.1 of this document, the low IF frequency of the OOK receiver denoted IF2 has been replaced by `fo`.

  The following setting is recommended:

  \[ fo = 100kHz \]

  `RXParam_PolyPfilt_"0011"`

  The value stored in `RXParam_ButterFilt` determines `fc`, the filter cut-off frequency. So the user should set `fc` according to:

  \[ 2 \times (fc - fo) > BW_{99\%,OOK} + LO_{drifts} \]

  Again, `fc` as a function of `RXParam_ButterFilt` is given in the section 3.4.6.

### 3.4.5. Channel Filters Setting in FSK Mode

`Fc`, the 3dB cutoff frequency of the Butterworth filter used in FSK reception, is programmed through the bit `RXParam_ButterFilt`. However, the whole receiver chain influences this cutoff frequency. Thus the channel select and resultant filter bandwidths are summarized in the following chart:
Table 37 suggests filter settings in FSK mode, along with the corresponding passive filter bandwidth and the accepted tolerance on the crystal reference.

### 3.4.6. Channel Filters Setting in OOK Mode

The center frequency, fo, is always set to 100kHz. The following chart shows the receiver bandwidth when changing RXParam_Butterfilt bits, whilst the polyphase filter is activated.

Table 38 suggests a few filter settings in OOK mode, along with the corresponding passive filter bandwidth and the accepted tolerance on the crystal reference.

### 3.4.7. RSSI

After filtering, the In-phase and Quadrature signals are amplified by a chain of 11 amplifiers, each with 6dB gain. The outputs of these amplifiers are used to evaluate the Received Signal Strength (RSSI).

#### 3.4.7.1. Resolution and Accuracy

Whilst the RSSI resolution is 0.5 dB, the absolute accuracy is not expected to be better than +/- 3dB due to process and external component variation. Higher accuracy whilst performing absolute RSSI measurements will require additional calibration.

#### 3.4.7.2. Acquisition Time
In OOK mode, the RSSI evaluates the signal strength by sampling I(t) and Q(t) signals 16 times in each period of the chosen IF2 frequency (refer to section 3.4.1). In FSK mode, the signals are sampled 16 times in each Fdev period, Fdev being the frequency deviation of the companion transmitter. An average is then performed over a sliding window of 16 samples. Hence, the RSSI output register RXParam_RSSI is updated 16 times in each Fdev or IF2 period.

The following settings should be respected:
- FSK Mode: Ensure that the Fdev parameter (as described in MCParam_Fdev) remains consistent with the actual frequency deviation of the companion transmitter.
- OOK reception: Ensure that the Fdev parameter (as described in MCParam_Fdev) is equal with the frequency of I(t) and Q(t) signals, i.e. the second Intermediate Frequency, IF2, of the receiver (Note that this equals Fo, the center frequency of the polyphase filter).

### 3.4.7.3. Dynamic Range

The dynamic range of the RSSI is over 70 dB, extending from the nominal sensitivity level. The IF gain setting available in MCParam_IF_gain is used to achieve this dynamic range:

![RSSI Dynamic Range Graph](image)

The RSSI response versus input signal is independent of the receiver filter bandwidth. However in the absence of any input signal, the minimum value directly reflects upon the noise floor of the receiver, which is dependent on the filter bandwidth of the receiver.

### 3.4.7.4. RSSI IRQ Source

The SX1211 can also be used to detect a RSSI level above a pre-configured threshold. The threshold is set in IRQParam_RSSI_irq_thresh and the IRQ status stored in IRQParam_RSSI_irq (cleared by writing a “1”).

An interrupt can be mapped to the IRQ0 or IRQ1 pins via bits IRQParam_Rx_stby_irq0 or IRQParam_Rx_stby_irq1. Figure 21 shows the timing diagram of the RSSI interrupt source, with IRQParam_RSSI_irq_thresh set to 28.
3.4.8. Fdev Setting in Receive Mode

The effect of the Fdev setting is different between FSK and OOK modes:

3.4.8.1. FSK Rx Mode

In FSK mode the Fdev setting, as configured by MCParam_Freq_Dev, sets sampling frequencies on the receiver. The user should make it consistent with the frequency deviation of the FSK signal that is received.

3.4.8.2. OOK Rx Mode

The frequency deviation Fdev, as described above, sets the sampling rate of the RSSI block. It is therefore necessary to set Fdev to the recommended low-IF frequency, IF2, of 100 kHz:

\[ F_{dev} = IF2 = 100kHz \]

\[ MCParam_{Freq}_{dev} = "00000011" \]

3.4.9. FSK Demodulator

The FSK demodulator provides data polarity information, based on the relative phase of the input I and Q signals at the baseband. Its outputs can be fed to the Bit Synchronizer to recover the timing information. The user can also use the raw, unsynchronized, output of the FSK demodulator in Continuous mode.

The FSK demodulator of the SX1211 operates most effectively for FSK signals with a modulation index greater than or equal to two:

\[ \beta = \frac{2 \times F_{dev}}{B_{R}} \geq 2 \]

3.4.10. OOK Demodulator

The OOK demodulator performs a comparison of the RSSI output and a threshold value. Three different threshold modes are available, programmed through the RXParam_OOK_thresh_type register.

The recommended mode of operation is the "Peak" threshold mode, illustrated below in Figure 22:
In peak threshold mode the comparison threshold level is the peak value of the RSSI, reduced by 6dB. In the absence of an input signal or during the reception of a logical “0”, the acquired peak value is decremented by one RXParam_OOK_thresh_step every RXParam_OOK_thresh_dec_period.

When the RSSI output is null for a long time (for instance after a long string of “0” received, or if no transmitter is present), the peak threshold level will continue falling until it reaches the “Floor Threshold” that is programmed through the register MCParam_OOK_floor_thresh.

The default settings of the OOK demodulator lead to the performance stated in the electrical specification. However, in applications in which sudden signal drops are awaited during a reception, the three parameters shall be optimized accordingly.

### 3.4.10.1. Optimizing the Floor Threshold

MCParam_OOK_floor_thres determines the sensitivity of the OOK receiver, as it sets the comparison threshold for weak input signals (i.e. those close to the noise floor). Significant sensitivity improvements can be generated if configured correctly.

Note that the noise floor of the receiver at the demodulator input depends on:
- The noise figure of the receiver.
- The gain of the receive chain from antenna to base band.
- The matching - including SAW filter.
- The bandwidth of the channel filters.

It is therefore important to note that the setting of MCParam_OOK_floor_thres will be application dependant. The following procedure is recommended to optimize MCParam_OOK_floor_thres.

![Figure 22: OOK Demodulator Description](image)
Set SX1211 in OOK Rx mode  
Adjust Bit Rate, Channel filter BW  
Default RXParam_OOK_thresh setting  
No input signal  
Continuous Mode

Monitor DATA pin (pin 20)

Increment MCPram_OOK_floor_thres

Glitch activity on DATA?

Optimization complete

Figure 23: Floor Threshold Optimization

The new floor threshold value found during this test should be the value used for OOK reception with those receiver settings.

Note that if the output signal on DATA is logic “1”, the value of MCPram_OOK_floor_thres is below the noise floor of the receiver chain. Conversely, if the output signal on DATA is logic “1”, the value of MAPram_floor_thres is several dB above the noise floor.

3.4.10.2. Optimizing OOK Demodulator Response for Fast Fading Signals

A sudden drop in signal strength can cause the bit error rate to increase. For applications where the expected signal drop can be estimated the following OOK demodulator parameters RXParam_OOK_thresh_step and RXParam_OOK_thresh_dec_period can be optimized as described below for a given number of threshold decrements per bit RXParam_OOK_thresh_dec_period:

- 000 → once in each chip period (d)
- 001 → once in 2 chip periods
- 010 → once in 4 chip periods
- 011 → once in 8 chip periods
- 100 → twice in each chip period
- 101 → 4 times in each chip period
- 110 → 8 times in each chip period
- 111 → 16 times in each chip period

For each decrement of RXParam_OOK_thresh_step:

- 000 → 0.5 dB (d)
- 001 → 1.0 dB
- 010 → 1.5 dB
- 011 → 2.0 dB
- 100 → 3.0 dB
- 101 → 4.0 dB
- 110 → 5.0 dB
- 111 → 6.0 dB
3.4.10.3. Alternative OOK Demodulator Threshold Modes

In addition to the Peak OOK threshold mode, the user can alternatively select two other types of threshold detectors:

- **Fixed threshold**: The value is selected through the MCParam_OOK_floor_thresh register (refer to section 3.4.10.1 for further information concerning optimization of the floor threshold).
- **Average threshold**: Data supplied by the RSSI block is averaged with the following cutoff frequency:

\[
RXParam\_OOK\_cutoff = 00 \Rightarrow F_{\text{cutoff}} = \frac{BR}{8 \pi}
\]

\[
RXParam\_OOK\_cutoff = 11 \Rightarrow F_{\text{cutoff}} = \frac{BR}{32 \pi}
\]

In the first example, the higher cut-off frequency enables a sequence of up to 8 consecutive “0” or “1” to be supported, whilst the lower cut-off frequency presented in the second example allows for the correct reception of up to 32 consecutive “0” or “1”.

3.4.11. Bit Synchronizer

The Bit Synchronizer (BitSync) is a block that provides a clean and synchronized digital output, free of glitches. The BitSync can be disabled through the bits RXParam_Bitsync_off, and by holding pin IRQ1 low. However, for optimum receiver performance, its use when running Continuous mode is strongly advised. With this option a DCLK signal is present on pin IRQ_1.

The BitSync is automatically activated in Buffered and Packet modes. The bit synchronizer bit-rate is controlled by MCParam_BR. For a given bit rate, this parameter is determined by:

\[
BR = \frac{F_{\text{XTAL}}}{64 \left[1 + \text{MCParam\_BR}\right]}
\]

Figure 24: BitSync Description
To ensure correct operation of the Bit Synchronizer, the following conditions have to be satisfied:

- A preamble (0x55 or 0xAA) of three bytes is required for synchronization, the longer the synchronization the better the packet success rate
- The subsequent payload bit stream must have at least one transition from '0' to '1' or '1' to '0' every 16 bits during data transmission
- The bit rate matching between the transmitter and the receiver must be better than 6.5%.

### 3.4.12. Alternative Settings

Bit Synchronizer and Active channel filter settings are a function of the reference oscillator crystal frequency, \( F_{XTAL} \). Settings other than those programmable with a 12.8 MHz crystal can be obtained by selection of the correct reference oscillator frequency. Please contact your local Semtech representative for further details.

### 3.4.13. Data Output

After OOK or FSK demodulation, the baseband signal is made available to the user on pin 20, DATA, when Continuous mode is selected.

In Buffered and Packet modes, the data is retrieved from the FIFO through the SPI interface.
4. Operating Modes

This section summarizes the settings for each operating mode of the SX1211, and explains the functionality available and the timing requirements for switching between modes.

4.1. Modes of Operation

Table 12: Operating Modes

5. Data Processing

5.1. Overview

5.1.1. Block Diagram

Figure 25 illustrates the SX1211 data processing circuit. Its role is to interface the data to/from the modulator/demodulator and the uC access points (SPI, IRQ and DATA pins). It also controls all the configuration registers.

The circuit contains several control blocks which are described in the following paragraphs.

The SX1211 implements several data operation modes, each with their own data path through the data processing section. Depending on the data operation mode selected, some control blocks are active whilst others remain disabled.

5.1.2. Data Operation Modes

The SX1211 has three different data operation modes selectable by the user:

- **Continuous mode**: each bit transmitted or received is accessed in real time at the DATA pin. This mode may be used if adequate external signal processing is available.

- **Buffered mode**: each byte transmitted or received is stored in a FIFO and accessed via the SPI bus. uC processing overhead is hence significantly reduced compared to Continuous mode operation. The packet length is unlimited.

- **Packet mode (recommended)**: user only provides/retrieves payload bytes to/from the FIFO. The packet is automatically built with preamble, Sync word, and optional CRC, DC free encoding and the reverse operation is performed in reception. The uC processing overhead is hence reduced further compared to Buffered mode. The maximum payload length is limited to the maximum FIFO limit of 64 bytes.
Table 14: Data Operation Mode Selection

<table>
<thead>
<tr>

<tbody>
<tr>
<td>00</td>
<td>Continuous</td>
</tr>
<tr>
<td>01</td>
<td>Buffered</td>
</tr>
<tr>
<td>1x</td>
<td>Packet</td>
</tr>
</tbody>
</table>

Each of these data operation modes is described fully in the following sections.

5.2. Control Block Description

5.2.1. SPI Interface

5.2.1.1. Overview

As illustrated in the Figure 26 below, the SX1211’s SPI interface consists of two sub blocks:

- SPI Config: used in all data operation modes to read and write the configuration registers which control all the parameters of the chip (operating mode, bit rate, etc...)
- SPI Data: used in Buffered and Packet mode to write and read data bytes to and from the FIFO. (FIFO interrupts can be used to manage the FIFO content.)

![Figure 26: SPI Interface Overview and uC Connections](image)

Both interfaces are configured in slave mode whilst the uC is configured as the master. They have separate selection pins (NSS_CONFIG and NSS_DATA) but share the remaining pins:

- SCK (SPI Clock): clock signal provided by the uC
- MOSI (Master Out Slave In): data input signal provided by the uC
- MISO (Master In Slave Out): data output signal provided by the SX1211

As described below, only one interface can be selected at a time with NSS_CONFIG having the priority:
Table 15: Config vs. Data SPI Interface Selection

<table>
<thead>
<tr>
<th>NSS_DATA</th>
<th>NSS_CONFIG</th>
<th>SPI Interface</th>
</tr>
</thead>
<tbody>
<tr>

<td>Data</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Config</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>None</td>
</tr>
</tbody>
</table>

The following paragraphs describe how to use each of these interfaces.

5.2.1.2. SPI Config

- Write Register
  To write a value into a configuration register the timing diagram below should be carefully followed by the uC. The register’s new value is effective from the rising edge of NSS_CONFIG.

  Figure 27: Write Register Sequence

Note that when writing more than one register successively, it is not compulsory to toggle NSS_CONFIG back high between two write sequences. The bytes are alternatively considered as address and value. In this instance, all new values will become effective on rising edge of NSS_CONFIG.

- Read Register
  To read the value of a configuration register the timing diagram below should be carefully followed by the uC.
5.2.1.3. SPI Data

- Write Byte (before/during Tx)

To write bytes into the FIFO the timing diagram below should be carefully followed by the uC.

Note that it is compulsory to toggle NSS_DATA back high between each byte written. The byte is pushed into the FIFO on the rising edge of NSS_DATA.
Read Byte (after/during Rx)
To read bytes from the FIFO the timing diagram below should be carefully followed by the uC.

```
+------------------+
| 12345678        |
| 1234567845678    |
+------------------+

NSS_DATA (In)
SCK (In)
MOSI (In)
MISO (Out)
HZ (input)
```

Figure 30: Read Bytes Sequence (ex: 2 bytes)

Note that it is compulsory to toggle NSS_DATA back high between each byte read.

5.2.2. FIFO

5.2.2.1. Overview and Shift Register (SR)

In Buffered and Packet modes of operation, both data to be transmitted and that has been received are stored in a configurable FIFO (First In First Out) device. It is accessed via the SPI Data interface and provides several interrupts for transfer management.

The FIFO is 1 byte (8 bits) wide hence it only performs byte (parallel) operations, whereas the demodulator functions serially. A shift register is therefore employed to interface the two devices. In transmit mode it takes bytes from the FIFO and outputs them serially (MSB first) at the programmed bit rate to the modulator. Similarly, in Rx the shift register gets bit by bit data from the demodulator and writes them byte by byte to the FIFO. This is illustrated in figure below.

```
+------------------+
| 1 2 3 4 5 6 7 8 |
| 1 2 3 4 5 6 7 8 |
+------------------+
```

Figure 31: FIFO and Shift Register (SR)

5.2.2.2. Size Selection

The FIFO width is programmable, to 16, 32, 48 or 64 bytes via MCParam_Fifo_size.
5.2.2.3. Interrupt Sources and Flags

All interrupt sources and flags are configured in the IRQParam section of the configuration register, with the exception of Fifo_threshold:

- **/Fifoempty**: /Fifoempty interrupt source is low when byte 0, i.e. whole FIFO, is empty. Otherwise it is high. Note that when retrieving data from the FIFO, /Fifoempty is updated on NSS_DATA falling edge, i.e. when /Fifoempty is updated to low state the currently started read operation must be completed. In other words, /Fifoempty state must be checked after each read operation for a decision on the next one (/Fifoempty = 1: more byte(s) to read; /Fifoempty = 0: no more byte to read).
- **Write_byte**: Write_byte interrupt source goes high for 1 bit period each time a new byte is transferred from the SR to the FIFO (i.e. each time a new byte is received)
- **Fifofull**: Fifofull interrupt source is high when the last FIFO byte, i.e. the whole FIFO, is full. Otherwise it is low.
- **Fifo_overrun_clr**: Fifo_overrun_clr flag is set when a new byte is written by the user (in Tx or Standby modes) or the SR (in Rx mode) while the FIFO is already full. Data is lost and the flag should be cleared by writing a 1, note that the FIFO will also be cleared.
- **Tx_done**: Tx_done interrupt source goes high when FIFO is empty and the SR’s last bit has been send to the modulator (i.e. the last bit of the packet has been sent). One bit period delay is required after the rising edge of Tx_done to ensure correct RF transmission of the last bit. In practice this may not require special care in the uC software due to IRQ processing time.
- **Fifo_threshold**: Fifo_threshold interrupt source’s behavior depends on the running mode (Tx, Rx or Stby mode) and the threshold itself can be programmed via MCParam_Fifo_thresh (B value). This behavior is illustrated in Figure 32.

5.2.3. Sync Word Recognition

5.2.3.1. Overview

Sync word recognition (also called Pattern recognition in previous products) is activated by setting RXParam_Sync_on. The bit synchronizer must also be activated.

The block behaves like a shift register; it continuously compares the incoming data with its internally programmed Sync word and asserts the Sync IRQ source on each occasion that a match is detected. This is illustrated in Figure 33.

```
Rx DATA (NRZ) Bit N-x = Sync_value[x] Bit N-1 = Sync_value[1] Bit N = Sync_value[0]
DCLK
SYNC
```

Figure 33: Sync Word Recognition

During the comparison of the demodulated data, the first bit received is compared with bit 7 (MSB) of byte at address 22 and the last bit received is compared with bit 0 (LSB) of the last byte whose address is determined by the length of the Sync word.

When the programmed Sync word is detected the user can assume that this incoming packet is for the node and can be processed accordingly.

5.2.3.2. Configuration

- **Size**: Sync word size can be set to 8, 16, 24 or 32 bits via RXParam_Sync_size. In Packet mode this field is also used for Sync word generation in Tx mode.
- **Error tolerance**: The number of errors tolerated in the Sync word recognition can be set to 0, 1, 2 or 3 via RXParam_Sync_tol.
- **Value**: The Sync word value is configured in SYNCParam_Sync_value. In Packet mode this field is also used for Sync word generation in Tx mode.

5.2.4. Packet Handler

The packet handler is the block used in Packet mode. Its functionality is fully described in section 5.5.

5.2.5. Control

The control block configures and controls the full chip’s behavior according to the settings programmed in the configuration registers.
5.3. Continuous Mode

5.3.1. General Description

As illustrated in Figure 34, in Continuous mode the NRZ data to (from) the (de)modulator is directly accessed by the uC on the bidirectional DATA pin (20). The SPI Data, FIFO and packet handler are thus inactive.

![Figure 34: Continuous Mode Conceptual View](image)

5.3.2. Tx Processing

In Tx mode, a synchronous data clock for an external uC is provided on IRQ_1 pin. Its timing with respect to the data is illustrated in Figure 35. DATA is internally sampled on the rising edge of DCLK so the uC can change logic state anytime outside the greyed out setup/hold zone.

The use of DCLK is compulsory in FSK and optional in OOK.

![Figure 35: Tx Processing in Continuous Mode](image)
5.3.3. Rx Processing

If the bit synchronizer is disabled, the raw demodulator output is made directly available on DATA pin and no DCLK signal is provided.

Conversely, if the bit synchronizer is enabled, synchronous cleaned data and clock are made available respectively on DATA and IRQ_1 pins. DATA is sampled on the rising edge of DCLK and updated on the falling edge as illustrated in Figure 36.

![Figure 36: Rx Processing in Continuous Mode](image)

Note that in Continuous mode it is always recommended to enable the bit synchronizer to clean the DATA signal even if the DCLK signal is not used by the uC. (bit synchronizer is automatically enabled in Buffered and Packet mode).

5.3.4. Interrupt Signals Mapping

The tables below give the description of the interrupts available in Continuous mode.

<table>
<thead>

</tr>
</tbody>
</table>

| IRQ_1 | DCLK |

Table 18: Interrupt Mapping in Continuous Tx Mode
5.3.5. uC Connections

Note that some connections may not be needed depending on the application:
- IRQ_0: if Sync and RSSI interrupts are not used. In this case, leave floating.
- IRQ_1: if the chip is never used in Tx FSK mode (DCLK connection is not compulsory in Rx and Tx OOK modes). In this case, leave floating.
- MISO: if no read register access is needed. In this case, pull-up to VDD through a 100 kΩ resistor.

In addition, NSS_DATA pin (unused in continuous mode) should be pulled-up to VDD through a 100 kΩ resistor. Please refer to Table 13 for SX1211’s pins configuration.

5.3.6. Continuous Mode Example

Configure all data processing related registers listed below appropriately. In this example we assume that both Bit synchronizer and Sync word recognition are on.

Table 19: Relevant Configuration Registers in Continuous Mode (data processing related only)

</tbody>
</table>

Tx Mode:
- Go to Tx mode (and wait for Tx to be ready, see Figure 50)
- Send all packet’s bits on DATA pin synchronously with DCLK signal provided on IRQ_1
- Go to Sleep mode

Rx Mode:
- Program Rx interrupts: IRQ_0 mapped to Sync (Rx_stby_irq_0="00") and IRQ_1 mapped to DCLK (Bit synchronizer enabled)
- Go to Rx mode (note that Rx is not ready immediately, see Figure 49)
- Wait for Sync interrupt
- Get all packet bits on DATA pin synchronously with DCLK signal provided on IRQ_1
- Go to Sleep mode
5.4. Buffered Mode

5.4.1. General Description

As illustrated in Figure 38, for Buffered mode operation the NRZ data to (from) the (de)modulator is not directly accessed by the uC but stored in the FIFO and accessed via the SPI Data interface. This frees the uC for other tasks between processing data from the SX1211, furthermore it simplifies software development and reduces uC performance requirements (speed, reactivity). Note that in this mode the packet handler stays inactive.

An important feature is also the ability to empty the FIFO in Stby mode, ensuring low power consumption and adding greater software flexibility.

![Figure 38: Buffered Mode Conceptual View](image)

Note that Bit Synchronizer is automatically enabled in Buffered mode. The Sync word recognition must be enabled (RXParam_Sync_on=1) independently of the FIFO filling method selected (IRQParam_Fifo_fill_method).

5.4.2. Tx Processing

After entering Tx in Buffered mode, the chip expects the uC to write into the FIFO, via the SPI Data interface, all the data bytes to be transmitted (preamble, Sync word, payload...).

Actual transmission of first byte will start either when the FIFO is not empty (i.e. first byte written by the uC) or when the FIFO is full depending on bit IRQParam_Tx_start_irq_0.

In Buffered mode the packet length is not limited, i.e. as long as there are bytes inside the FIFO they are sent. When the last byte is transferred to the SR, /Fifoempty IRQ source is asserted to warn the uC, at that time FIFO can still be filled with additional bytes if needed.

When the last bit of the last byte has left the SR (i.e. 8 bit periods later), the Tx_done interrupt source is asserted and the user can exit Tx mode after waiting at least 1 bit period from the last bit processed by modulator.
If the transmitter is switched off (for example due to entering another chip mode) during transmission it will stop immediately, even if there is still unsent data.

Figure 39 illustrates Tx processing with a 16 byte FIFO depth and Tx_start_irq_0=0. Please note that in this example the packet length is equal to FIFO size, but this does not need to be the case, the uC can use the FIFO interrupts anytime during Tx to manage FIFO contents and write additional bytes.

5.4.3. Rx Processing

After entering Rx in Buffered mode, the chip requires the uC to retrieve the received data from the FIFO. The FIFO will actually start being filled with received bytes either; when a Sync word has been detected (in this case only the bytes following the Sync word are filled into the FIFO) or when the Fifo_fill bit is asserted by the user - depending on the state of bit, IRQParam_Fifo_fill_method.

In Buffered mode, the packet length is not limited i.e. as long as Fifo_fill is set, the received bytes are shifted into the FIFO.

The uC software must therefore manage the transfer of the FIFO contents by interrupt and ensure reception of the correct number of bytes. (In this mode, even if the remote transmitter has stopped, the demodulator will output random bits from noise)

When the FIFO is full, Fifofull IRQ source is asserted to alert the uC, that at that time, the FIFO can still be unfilled without data loss. If the FIFO is not unfilled, once the SR is also full (i.e. 8 bits periods later) Fifo_overrun_clr is asserted and SR’s content is lost.

Figure 40 illustrates an Rx processing with a 16 bytes FIFO size and Fifo_fill_method=0. Please note that in the illustrative example of section 5.4.6, the uC does not retrieve any byte from the FIFO through SPI Data, causing overrun.
5.4.4. Interrupt Signals Mapping

The tables below describe the interrupts available in Buffered mode.

<table>
<thead>

5.4.5. uC Connections

![Diagram of SX1211 and uC connections]

Figure 41: uC Connections in Buffered Mode

Note that depending upon the application, some uC connections may not be needed:
- IRQ_0: if none of the relevant IRQ sources are used. In this case, leave floating.
- IRQ_1: if none of the relevant IRQ sources are used. In this case, leave floating.
- MISO: if no read register access is needed and the chip is used in Tx mode only. In this case, pull up to VDD through a 100 kΩ resistor.

In addition, DATA pin (unused in buffered mode) should be pulled-up to VDD through a 100 kΩ resistor. Please refer to Table 13 for the SX1211’s pin configuration.

5.4.6. Buffered Mode Example

- Configure all data processing related registers listed below appropriately. In this example we assume Sync word recognition is on and Fifo_fill_method=0.

Table 22: Relevant Configuration Registers in Buffered Mode (data processing related only)

Tx Mode:
- Program Tx start condition and IRQs: Start Tx when FIFO is not empty (Tx_start_irq_0=1) and IRQ_1 mapped to Tx_done (Tx_irq_1=1)
- Go to Tx mode (and wait for Tx to be ready, see Figure 50)
Write packet bytes into FIFO. Tx starts when the first byte is written (Tx_start_irq_0=1). We assume the FIFO is being filled via SPI Data faster than being unfilled by SR.

Wait for Tx_done interrupt (+1 bit period)

Go to Sleep mode

Rx Mode:

Program Rx/Stby interrupts: IRQ_0 mapped to /Fifoempty (Rx_stby_irq_0=10) and IRQ_1 mapped to Fifo_threshold (Rx_stby_irq_1=11). Configure Fifo_thresh to an appropriate value (ex: to detect packet end if its length is known)

Go to Rx mode (note that Rx is not ready immediately, Cf section 7.3.1).

Wait for Fifo_threshold interrupt (i.e. Sync word has been detected and FIFO filled up to the defined threshold).

If it is packet end, go to Stby (SR’s content is lost).

Read packet bytes from FIFO until /Fifoempty goes low (or correct number of bytes is read).

Go to Sleep mode.
5.5. Packet Mode

5.5.1. General Description

Similar to Buffered mode operation, in Packet mode the NRZ data to (from) the (de)modulator is not directly accessed by the uC but stored in the FIFO and accessed via the SPI Data interface.

In addition, the SX1211’s packet handler performs several packet oriented tasks such as Preamble and Sync word generation, CRC calculation/check, whitening/dewhiten ing of data, address filtering, etc. This simplifies still further software and reduces uC overhead by performing these repetitive tasks within the RF chip itself.

Another important feature is ability to fill and empty the FIFO in Stby mode, ensuring optimum power consumption and adding more flexibility for the software.

![Packet Mode Conceptual View](image)

Note that Bit Synchronizer and Sync word recognition are automatically enabled in Packet mode.

5.5.2. Packet Format

Two types of packet formats are supported: fixed length and variable length, selectable by the PKTParam_Pkt_format bit. The maximum size of the payload is limited by the size of the FIFO selected (16, 32, 48 or 64 bytes).

5.5.2.1. Fixed Length Packet Format

In applications where the packet length is fixed in advance, this mode of operation may be of interest to minimize RF overhead (no length byte field is required). All nodes, whether Tx only, Rx only, or Tx/Rx should be programmed with the same packet length value.

The length of the payload is set by the PKTParam_Payload_length register and is limited by the size of the FIFO selected.
The length stored in this register relates only to the payload which includes the message and the optional address byte. In this mode, the payload must contain at least one byte, i.e. address or message byte.

An illustration of a fixed length packet is shown in Figure 43. It contains the following fields:
- Preamble (1010…).
- Sync word (Network ID).
- Optional Address byte (Node ID).
- Message data.
- Optional 2-bytes CRC checksum.

![Figure 43: Fixed Length Packet Format](image)

### 5.5.2.2. Variable Length Packet Format

This mode is necessary in applications where the length of the packet is not known in advance and can vary over time. It is then necessary for the transmitter to send the length information together with each packet in order for the receiver to operate properly.

In this mode the length of the payload, indicated by the length byte in Figure 44, is given by the first byte of the FIFO and is limited only by the width of the FIFO selected. Note that the length byte itself is not included in its calculation. In this mode, the payload must contain at least 2 bytes, i.e. length + address or message byte.

An illustration of a variable length packet is shown in Figure 44. It contains the following fields:
- Preamble (1010…).
- Sync word (Network ID).
- Length byte
- Optional Address byte (Node ID).
- Message data.
- Optional 2-bytes CRC checksum.
5.5.3. Tx Processing

In Tx mode the packet handler dynamically builds the packet by performing the following operations on the payload available in the FIFO:

- Add a programmable number of preamble bytes
- Add a programmable Sync word
- Optionally calculating CRC over complete payload field (optional length byte + optional address byte + message) and appending the 2 bytes checksum.
- Optional DC-free encoding of the data (Manchester or whitening).

Only the payload (including optional address and length fields) is to be provided by the user in the FIFO.

Assuming that the chip is already in Tx mode then, depending on IRQParam_Tx_start_irq_0 bit, packet transmission (starting with programmed preamble) will start either after the first byte is written into the FIFO (Tx_start_irq_0=1) or after the number of bytes written reaches the user defined threshold (Tx_start_irq_0=0). The FIFO can also be fully or partially filled in Stby mode via PKTParam_Fifo_stby_access. In this case, the start condition will only be checked when entering Tx mode.

At the end of the transmission (Tx_done = 1), the user must explicitly exit Tx mode if required. (e.g. back to Stby)

Note that while in Tx mode, before and after actual packet transmission (not enough bytes or Tx_done), additional preamble bytes are automatically sent to the modulator. When the start condition is met, the current additional preamble byte is completely sent before the transmission of the next packet (i.e. programmed preamble) is started.

5.5.4. Rx Processing

In Rx mode the packet handler extracts the user payload to the FIFO by performing the following operations:

- Receiving the preamble and stripping it off.
- Detecting the Sync word and stripping it off.
- Optional DC-free decoding of data.
- Optionally checking the address byte.
- Optionally checking CRC and reflecting the result on CRC_status bit and CRC_OK IRQ source.

Only the payload (including optional address and length fields) is made available in the FIFO.

Payload_ready and CRC_OK interrupts (the latter only if CRC is enabled) can be generated to indicate the end of the packet reception.
By default, if the CRC check is enabled and fails for the current packet, then the FIFO is automatically cleared and neither of the two interrupts are generated and new packet reception is started. This autoclear function can be disabled via PKTParam_CRC_autoclr bit and, in this case, even if CRC fails, the FIFO is not cleared and only Payload_ready IRQ source is asserted.

Once fully received, the payload can also be fully or partially retrieved in Stby mode via PKTParam_Fifo_stby_access. At the end of the reception, although the FIFO automatically stops being filled, it is still up to the user to explicitly exit Rx mode if required. (e.g. go to Stby to get payload). FIFO must be empty for a new packet reception to start.

5.5.5. Packet Filtering

SX1211’s packet handler offers several mechanisms for packet filtering ensuring that only useful packets are made available to the uC, reducing significantly system power consumption and software complexity.

5.5.5.1. Sync Word Based

Sync word filtering/recognition is automatically enabled in Packet mode. It is used for identifying the start of the payload and also for network identification. As previously described, the Sync word recognition block is configured (size, error tolerance, value) via RXParam_SYNC_size, RXParam_SYNC_tol and SyncParam configuration registers. This information is used, both for appending Sync word in Tx, and filtering packets in Rx.

Every received packet which does not start with this locally configured Sync word is automatically discarded and no interrupt is generated.

When the Sync word is detected, payload reception automatically starts and Sync IRQ source is asserted.

5.5.5.2. Address Based

Address filtering can be enabled via the PKTParam_Adrs_filt bits. It adds another level of filtering, above Sync word, typically useful in a multi-node networks where a network ID is shared between all nodes (Sync word) and each node has its own ID (address).

Three address based filtering options are available:

- **Adrs_filt = 01**: Received address field is compared with internal register Node_Adrs. If they match then the packet is accepted and processed, otherwise it is discarded.
- **Adrs_filt = 10**: Received address field is compared with internal register Node_Adrs and the constant 0x00. If either is a match, the received packet is accepted and processed, otherwise it is discarded. This additional check with a constant is useful for implementing broadcast in a multi-node networks.
- **Adrs_filt = 11**: Received address field is compared with internal register Node_Adrs and the constants 0x00 & 0xFF. If any of the three matches, then the received packet is accepted and processed, otherwise it is discarded. These additional checks with constants are useful for implementing broadcast commands of all nodes.

Please note that the received address byte, as part of the payload, is not stripped off the packet and is made available in the FIFO. In addition, Node_Adrs and Adrs_filt only apply to Rx. On Tx side, if address filtering is expected, the address byte should simply be put into the FIFO like any other byte of the payload.

5.5.5.3. Length Based

In variable length Packet mode, PKTParam_Payload_length must be programmed with the maximum length permitted. If received length byte is smaller than this maximum then the packet is accepted and processed, otherwise it is discarded.
Please note that the received length byte, as part of the payload, is not stripped off the packet and is made available in the FIFO.

To disable this function the user should set the value of the PKTParam_Payload_length to the value of the FIFO size selected.

5.5.5.4. CRC Based

The CRC check is enabled by setting bit PKTParam_CRC_on. It is used for checking the integrity of the message.
- On Tx side a two byte CRC checksum is calculated on the payload part of the packet and appended to the end of the message.
- On Rx side the checksum is calculated on the received payload and compared with the two checksum bytes received. The result of the comparison is stored in the PKTParam_CRC_status bit and CRC_OK IRQ source.

By default, if the CRC check fails then the FIFO is automatically cleared and no interrupt is generated. This filtering function can be disabled via PKTParam_CRC_autoclr bit and in this case, even if CRC fails, the FIFO is not cleared and only Payload_ready interrupt goes high. Please note that in both cases, the two CRC checksum bytes are stripped off by the packet handler and only the payload is made available in the FIFO.

The CRC is based on the CCITT polynomial as shown in Figure 45. This implementation also detects errors due to leading and trailing zeros.

\[
\text{CRC Polynomial} = X^{16} + X^{12} + X^5 + 1
\]

Figure 45: CRC Implementation

5.5.6. DC-Free Data Mechanisms

The payload to be transmitted may contain long sequences of 1’s and 0’s, which introduces a DC bias in the transmitted signal. The radio signal thus produced has a non uniform power distribution over the occupied channel bandwidth. It also introduces data dependencies in the normal operation of the demodulator. Thus it is useful if the transmitted data is random and DC free.

For such purposes, two techniques are made available in the packet handler: Manchester encoding and data whitening. Please note that only one of the two methods should be enabled at a time.

5.5.6.1. Manchester Encoding

Manchester encoding/decoding is enabled by setting bit PKTParam_Manchester_on and can only be used in Packet mode.

The NRZ data is converted to Manchester code by coding ‘1’ as “10” and ‘0’ as “01”.

In this case, the maximum chip rate is the maximum bit rate given in the specifications section and the actual bit rate is half the chip rate.
Manchester encoding and decoding is only applied to the payload and CRC checksum while preamble and Sync word are kept NRZ. However, the chip rate from preamble to CRC is the same and defined by MCParam_BR (Chip Rate = Bit Rate NRZ = 2 x Bit Rate Manchester).

Manchester encoding/decoding is thus made transparent for the user, who still provides/retrieves NRZ data to/from the FIFO.

<table>

<td>1 0 0 0 1 1 ...</td>
</tr>
</tbody>
</table>

*Figure 46: Manchester Encoding/Decoding*

5.5.6.2. Data Whitening

Another technique called whitening or scrambling is widely used for randomizing the user data before radio transmission. The data is whitened using a random sequence on the Tx side and de-whitened on the Rx side using the same sequence. Comparing to Manchester technique it has the advantage of keeping NRZ datarate i.e. actual bit rate is not halved.

The whitening/de-whitening process is enabled by setting bit PKTParam_Whitening_on. A 9-bit LFSR is used to generate a random sequence. The payload and 2-byte CRC checksum is then XORed with this random sequence as shown in Figure 47. The data is de-whitened on the receiver side by XORing with the same random sequence.

Payload whitening/de-whitening is thus made transparent for the user, who still provides/retrieves NRZ data to/from the FIFO.

5.5.8. uC Connections

**Figure 48: uC Connections in Packet Mode**

Note that depending upon the application, some uC connections may not be needed:
- IRQ_0: if none of the relevant IRQ sources are used. In this case, leave floating.
- IRQ_1: if none of the relevant IRQ sources are used. In this case, leave floating.
- MISO: if no read register access is needed and the chip is used in Tx mode only. In this case, pull up to VDD through a 100 kΩ resistor.

In addition, DATA pin (unused in packet mode) should be pulled-up to VDD through a 100 kΩ resistor. Please refer to Table 13 for the SX1211’s pin configuration.
5.5.9. Packet Mode Example

- Configure all data processing related registers listed below appropriately. In this example we assume CRC is enabled with autoclear on.

<td>FIFO_stby_access</td>
</tr>
</tbody>
</table>

**(1)** fixed format only

**Tx Mode:**
- Program Tx start condition and IRQs: Start Tx when FIFO not empty (Tx_start_irq_0=1) and IRQ_1 mapped to Tx_done (Tx_irq_1=1)
- Go to Stby mode
- Write all payload bytes into FIFO (Fifo_stby_access=0, Stby interrupts can be used if needed)
- Go to Tx mode. When Tx is ready (automatically handled) Tx starts (Tx_start_irq_0=1).
- Wait for Tx_done interrupt (+1 bit period)
- Go to Sleep mode

**Rx Mode:**
- Program Rx/Stby interrupts: IRQ_0 mapped to FIFOempty (Rx_stby_irq_0=10) and IRQ_1 mapped to CRC_OK (Rx_stby_irq_1=00)
- Go to Rx (note that Rx is not ready immediately, see section 7.3.1
- Wait for CRC_OK interrupt
- Go to Stby
- Read payload bytes from FIFO until FIFOempty goes low. (Fifo_stby_access =1)
- Go to Sleep mode

5.5.10. Additional Information

If the number of bytes filled for transmission is greater than the actual length of the packet to be transmitted and Tx_start_irq_0 = 1, then the FIFO is cleared after the packet has been transmitted. Thus the extra bytes in the
FIFO are lost. On the other hand if Tx_start_irq_0 = 0 then the extra bytes are kept into the FIFO. This opens up the possibility of transmitting more than one packet by filling the FIFO with multiple packet messages.

It is not possible to receive multiple packets. Once a packet has been received and filled into the FIFO all its content needs to be read i.e. the FIFO must be empty for a new packet reception to be initiated.

The Payload_ready interrupt goes high when the last payload byte is available in the FIFO and remains high until all its data are read. Similar behavior is applicable to Adrs_match and CRC_OK interrupts.

The CRC result is available in the CRC_status bit as soon as the CRC_successful and Payload_ready interrupt sources are triggered. In Rx mode, CRC_status is cleared when the complete payload has been read from the FIFO. If the payload is read in Stby mode, then CRC_status is cleared when the user goes back to Rx mode and a new Sync word is detected.

The Fifo_fill_method and Fifo_fill bits don’t have any meaning in the Packet mode and should be set to their default values only.
6. Configuration and Status Registers

6.1. General Description

Table 26 sums-up the control and status registers of the SX1211:

Table 26: Registers List

### Description

**PassiveFilt**
- Bit 0-3: Value for setting the passive filter bandwidth.
- Typical values:
  - `0000`: 65 kHz
  - `0001`: 82 kHz
  - `0010`: 109 kHz
  - `0011`: 137 kHz
  - `0100`: 157 kHz
  - `0101`: 184 kHz
  - `0110`: 211 kHz
  - `0111`: 234 kHz
  - `1000`: 262 kHz
  - `1001`: 294 kHz
  - `1010`: 321 kHz
  - `1011`: 378 kHz
  - `1100`: 414 kHz
  - `1101`: 458 kHz
  - `1110`: 514 kHz
  - `1111`: 676 kHz

**ButterFilt**
- Bit 0-3: Value for setting the receiver bandwidth.
- Formula:
  
  \[ f_c = f_0 + 200 kHz \times \frac{f_{\text{ref}} MHz}{12.8 MHz} \left(1 + \frac{\text{Val}(\text{ButterFilt})}{8}\right) \]

**PolypFilt_center**
- Bit 0-3: Value for setting the central frequency of the polyphase filter.
- Formula:
  
  \[ f_0 = 200 kHz \times \frac{f_{\text{ref}} MHz}{12.8 MHz} \left(1 + \frac{\text{Val}(\text{PolypFilt_center})}{8}\right) \]

**Bitsync_off**
- Bit 0: Bit synchronizer: control in Continuous Rx mode.
- 1: on
- 0: off

**Sync_on**
- Bit 0: Sync word recognition.
- 1: on
- 0: off

**Sync_size**
- Bit 0-3: Sync word size.
- Values:
  - 00: 8 bits
  - 01: 16 bits
  - 10: 24 bits
  - 11: 32 bits

**Sync_tol**
- Bit 0-1: Number of errors tolerated in the Sync word recognition.
- Values:
  - 00: 0 error
  - 01: 1 error
  - 10: 2 errors
  - 11: 3 errors

7. Application Information

7.1. Crystal Resonator Specification

Table 34 shows the crystal resonator specification for the crystal reference oscillator circuit of the SX1211. This specification covers the full range of operation of the SX1211 and is employed in the reference design (see section 7.5.3).

Table 34: Crystal Resonator Specification

</table>

Note that the initial frequency tolerance, temperature stability and ageing performance should be chosen in accordance with the target operating temperature range and the receiver bandwidth selected.

7.2. Software for Frequency Calculation

The R1, P1, S1, and R2, P2, S2 dividers are configured over the SPI interface and programmed by 8 bits each, at addresses 6 to 11. The frequency pairs may hence be switched in a single SPI cycle.

7.2.1. GUI

To aid the user with calculating appropriate R, P and S values, software is available to perform the frequency calculation. The SX1211 PLL frequency Calculator Software can be downloaded from the Semtech website.

7.2.2. .dll for Automatic Production Bench

The Dynamically Linked Library (DLL) used by the software to perform these calculations is also provided, free of charge, to users, for inclusion in automatic production testing. Key benefits of this are:

- No hand trimming of the reference frequency required: the actual reference frequency of the Device Under Test (DUT) can be easily measured (e.g. from the CLKOUT output of the SX1211) and the tool will calculate the best frequencies to compensate for the crystal initial error.
- Channel plans can be calculated and stored in the application’s memory, then adapted to the actual crystal oscillator frequency.

7.3. Switching Times and Procedures

As an ultra-low power device, the SX1211 can be configured for low minimum average power consumption. To minimize consumption the following optimized transitions between modes are shown.
7.3.1. Optimized Receive Cycle

The lowest-power Rx cycle is the following:

- Set SX1211 in Standby mode
- Wait for XO settling
- Set SX1211 in FS mode
- Wait for PLL settling
- Set SX1211 in Rx mode
- Wait for Receiver settling

Receiver is ready:
- RSSI sampling is valid after a 1/Fdev period
- Received data is valid

SX1211 can be put in any other mode

Figure 49: Optimized Rx Cycle

Note: If the lock detect indicator is available on an external interrupt pin of the companion uC, it can be used to optimize TS_FS, without having to wait the maximum specified TS_FS.
7.3.2. Optimized Transmit Cycle

Note: As stated in the preceding section, TS_FS time can be improved by using the external lock detector pin as external interrupt trigger.
7.3.3. Transmitter Frequency Hop Optimized Cycle

Figure 51: Tx Hop Cycle
7.3.4. Receiver Frequency Hop Optimized Cycle

**Figure 52: Rx Hop Cycle**

Note: it is also possible to move from one channel to the other one without having to switch off the receiver. This method is faster, and overall draws more current. For timing information, please refer to TS_RE_HOP on Table 8.
7.3.5. Rx→Tx and Tx→Rx Jump Cycles

SX1211

IDDR
3.0mA typ.

IDD'T
16mA typ. @1dBm

Set SX1211 in Rx mode

Wait
TS TR

SX1211 is now ready for data transmission

Set SX1211 in Tx mode

SX1211 is ready to receive data

Figure 53: Rx → Tx → Rx Cycle
7.4. Reset of the Chip

A power-on reset of the SX1211 is triggered at power up. Additionally, a manual reset can be issued by controlling pin 13.

7.4.1. POR

If the application requires the disconnection of VDD from the SX1211, despite of the extremely low Sleep Mode current, the user should wait for 10 ms from of the end of the POR cycle before commencing communications over the SPI bus. Pin 13 (TEST8) should be left floating during the POR sequence.

![POR Timing Diagram](image1)

Please note that any CLKOUT activity can also be used to detect that the chip is ready.

7.4.2. Manual Reset

A manual reset of the SX1211 is possible even for applications in which VDD cannot be physically disconnected. Pin 13 should be pulled high for a hundred microseconds, and then released. The user should then wait for 5 ms before using the chip.

![Manual Reset Timing Diagram](image2)

Please note that while pin 13 is driven high, an over current consumption of up to ten milliamps can be seen on VDD.
7.5. Reference Design

It is recommended that this reference design (i.e. schematics, placement, layout, BOM,) is replicated in the final application board to guarantee optimum performance.

7.5.1. Application Schematic

![Reference Design Circuit Schematic]

The reference design area is represented by the dashed rectangle. C12 is a DC blocking capacitor which protects the SAW filter. It has been added for debug purposes could be removed for a direct antenna connection if there is no DC bias is expected at the antenna port. Please note that C10 and C11 are not used.

7.5.2. PCB Layout

As illustrated in figures below, the layout has the following characteristics:

- very compact (9x19mm) => can be easily inserted even on very small PCBs
- standard PCB technology (2 layers, 1.6mm, std via & clearance) => low cost
- Its performance is quasi-insensitive to dielectric thickness => minimal design effort to transfer to other PCB technologies (thickness, # of layers, etc...)
The layers description is illustrated in Figure 57:

![Layer Description Diagram](image1)

**Figure 57: Reference Design’s Stackup**

The layout itself is illustrated in Figure 58. Please contact Semtech for gerber files.

![Layout Diagram](image2)

*Not part of the ref. design (not required for direct antenna connection).

Note: for battery powered applications, a high value capacitance should be implemented in parallel with C1 (typically 10 µF) to offer a low impedance voltage source during startup sequences.
7.5.4. SAW Filter Plot

The following screenshot shows the plot of the SAW filter used on the reference design:

7.6. Reference Design Performance

All the measurements visible on section 7.6 typical figures obtained under the following conditions, unless otherwise noted:

- Nominal VDD = 3.3 V
- Tests performed at room temperature: 25°C +/-3°C
- Center frequency 869 MHz or 915 MHz
- \(R, P, S\) triplets are those calculated by the software described in section 3.2.8.
- All register settings are default, except for those stated in the relevant sub-sections
- Maximum Output Power programmed on Pout tests
- All sensitivities are evaluated in Continuous mode, demodulating a PN15 sequence, BER=0.1%
- FSK sensitivities measured at 25kbps, Fdev=+/-50 kHz
- OOK sensitivities measured at 8kbps, with Fo=100 kHz. IF2 set to 100 kHz.
- On all Adjacent Channel Rejection (ACR), Blocking and Spurious Response Frequency tests, the unwanted signal is unmodulated.
- Bill of Materials as shown in section 7.5.3. In particular, a SAW filter is used (see its performance on section 7.5.4)
- The filter settings described on Table 37 and Table 38 were used for the measurements of section 7.6.5.

7.6.1. Sensitivity Flatness

Notes:
- Measured in FSK mode only. OOK sensitivity characteristics will be similar.
- The sensitivity difference along the band remains inside the ripple performance of the SAW filter (the nominal passband of the 869 MHz SAW filter is 868 – 870 MHz)
- The SAW filter ripple response is referenced to its insertion loss at 869 MHz and 915 MHz for each filter.
7.6.2. Sensitivity vs. LO Drift

**Figure 63: FSK Sensitivity Loss vs. LO Drift**

**Figure 64: OOK Sensitivity Loss vs. LO Drift**

Notes:
- In FSK Mode, the default filter setting (“A3” at address $16$) is kept, leading to $F_c=96$ kHz typ.
- In OOK Mode, “F3” is set at address $16$, leading to $(F_c-F_o)=95$ kHz typ.
- The above ensures that the channel filter is wide enough, therefore characterizing the demodulator response, and NOT the filter response.
7.6.3. Sensitivity vs. Receiver BW

**Figure 65: FSK Sensitivity vs. Rx BW**

**Figure 66: OOK Sensitivity Change vs. Rx BW**
7.6.4. Sensitivity Stability over Temperature and Voltage

![Sensitivity Stability Chart]

**Figure 67: Sensitivity Stability**

Note:
- The sensitivity performance is very stable over the VDD range, and the effect of high temperature is minimal.

7.6.5. Sensitivity vs. Bit Rate

![Sensitivity vs. Bit Rate Chart]

**Figure 68: FSK Sensitivity vs. BR**
7.6.6. Adjacent Channel Rejection

Figure 69: OOK Sensitivity vs. BR

Figure 70: ACR in FSK Mode
Notes:

- In FSK mode, the unwanted signal is unmodulated (as described in the EN 300-220 V2.1.1). Co-Channel Rejection (CCR, Offset = 0kHz) is positive due to the DC cancellation process of the zero-IF architecture.
- In OOK mode, the polyphase filter efficiency is limited, thus limiting the adjacent channel rejection at 2xFo distance.

7.6.7. Output Power Flatness

Figure 71: ACR in OOK Mode

Figure 72: Pout for 869 MHz Band Operation
Notes:
- As noted in section 7.5.4, the 869 MHz SAW filter does not cover the whole European 863 – 870 MHz frequency band when used in a 50 ohms environment. Hence the output power degradation at the lowest frequencies. For applications in the 863 – 870 MHz band it is recommended that an appropriate SAW filter be implemented or that the SAW response tuned by external matching.
- The SAW filter ripple references are the insertion loss of each SAW at 869 MHz and 915 MHz.

7.6.8. Pout and IDD vs. PA Setting

Figure 73: Pout for 915 MHz Band Operation

Figure 74: Pout and IDD at all PA Settings, 869 MHz
Figure 75: Pout and IDD at all PA Settings, 915 MHz

Note:
- +10dBm typ. Output power is achievable, even at SAW filter’s output.

7.6.9. Pout Stability over Temperature and Voltage

Figure 76: Pout Stability

The output power is not sensitive to the supply voltage, and it decreases slightly when temperature rises.
7.6.10. Transmitter Spectral Purity

**Figure 77: 869 MHz Spectral Purity DC-1GHz**

**Figure 78: 869 MHz Spectral Purity 1-6GHz**
7.6.11. OOK Channel Bandwidth

The OOK bit rate ranges form 1.56 to 16.7 kbps. It is interesting to note that, for the lowest bit rates, a channel spacing approaching 200 kHz is achievable:

![Figure 79: OOK Spectrum - 2kbps](image1)

![Figure 80: OOK Spectrum - 8kbps](image2)

![Figure 81: OOK Spectrum - 16.7kbps](image3)

Notes:
- The test conditions are: Fdev=100 kHz, TXParam_InterpFilt = 200 kHz
7.6.12. FSK Spectrum in Europe

Figure 82 shows the minimal spectral occupation achievable in the European band, keeping in mind that the minimum frequency deviation that a SX1211 receiver can accept is 33 kHz. If the companion receiver can bear smaller frequency deviations, the range of modulation bandwidth can be further decreased.

![Figure 82: FSK - 1.56kbps - +/-33 kHz](image1)

The default configuration of the SX1211 yields the bandwidth visible on Figure 83:

![Figure 83: FSK - 25 kbps - +/-50 kHz](image2)

Figure 84 shows the maximal bit rate and frequency deviation that can fit in the 868 to 868.6 MHz European sub-band:

![Figure 84: FSK - 40 kbps - +/-40 kHz](image3)
7.6.13. Digital Modulation Schemes

FCC Part 15.247 allows for systems employing digital modulation techniques to transmit up to 1 W, provided that the 6 dB bandwidth of the signal is at least 500 kHz and that the power spectral density does not exceed 8dBm in any 3 kHz bandwidth.

The SX1211 can actually meet these constraints whilst transmitting at the maximum output power of the device of typ. 10dBm, thanks to the built-in whitening process described in section 5.5.6.2:

Conditions:
- \( P_{out} = +10.6\text{dBm} \)
- \( F_{dev} = +/-200\text{kHz} \)
- \( BR=100\text{ kbps} \) (Chip rate=100kCps, as data whitening is enabled)
- Packet mode, data whitening enabled

Note: Manchester encoding allows meeting an even lower power spectral density, at the expense of the bit rate efficiency.

Figure 87: IDD vs. Temp and VDD
8. Packaging Information

8.1. Package Outline Drawing

SX1211 is available in a 32-lead TQFN package as shown in Figure 88 below.

9. Revision History

Revision 5
- Increase maximum Bit Rate in FSK
- Update minimum XO frequency
- Add the manual reset description
- Insert decoupling recommendation for battery operated systems
- Add Tools ordering information

Revision 6
- Update SPI speed
- Clarify default fc value in Table 29
- Clarify MISO state in SPI timing figures
- Improve ESD rating description

Revision 7
- Describe PLL_LOCK pin state in Table 13
- Improve note in section 5.4.1
- Clarify Table 5 measurement conditions
- Clarify /Fifoempty interrupt source behavior
- Correct Vtune in Figure 5
- Adjust VCO tuning range in section 3.2.5.2

Revision 8
- Add Wafer form ordering information
- Update tools ordering information
- Update Bit Synchronizer description
